Compare

Test

Conditions

Set

Jumps

Jump Tables

## Conditional Commands

Conditional Jumps

Conditional Moves

## Logic Structures

Conditional Branches (if)

Loops (for, while)

Switch Statements (switch)

## Exercises

- ▶ Definition: A register storing the address of the next command.
- ▶ Only an **abstract concept**; Has different implementations, like %rip(RIP) in x86.

# Program Counter

## Commands

### Program Counter

Condition Codes

Compare

Test

Conditions

Set

Jumps

Jump Tables

## Conditional Commands

Conditional Jumps

Conditional Moves

## Logic Structures

Conditional Branches (if)

Loops (for, while)

Switch Statements (switch)

## Exercises

- ▶ Definition: A register storing the address of the next command.
- ▶ Only an **abstract concept**; Has different implementations, like %rip(RIP) in x86.
- ▶ Cannot be directly written (read-only).

# Program Counter

- ▶ Definition: A register storing the address of the next command.
- ▶ Only an **abstract concept**; Has different implementations, like %rip(RIP) in x86.
- ▶ Cannot be directly written (read-only).

## Remark

*Can be used to access data stored in memory with relative address difference.*

## Example

```
movq 8(%rip) %rax
```

### Commands

## Logic Structures

Conditional Branches (if)

Loops (for, while)

Switch Statements (switch)

## Exercises

The state of condition code depends on the result of the last arithmetic command.

# How condition codes are set?

The state of condition code depends on the result of the last arithmetic command.

## Example

Suppose all the flags are 0 at first, doing

```
sub %rax %rax
```

```
mov %rbx %rax
```

only changes ZF to be 1.

# How condition codes are set?

The state of condition code depends on the result of the last arithmetic command.

## Example

Suppose all the flags are 0 at first, doing

```
sub %rax %rax
```

```
mov %rbx %rax
```

only changes ZF to be 1.

## Remark

*leaq doesn't change the condition code.*

## Conditional Commands

Conditional Jumps

Conditional Moves

## Logic Structures

Conditional Branches (if)

Loops (for, while)

Switch Statements (switch)

## Exercises

To implement more complicated structures while minimizing the size of the assembly program, jumps are introduced.

## definition

`jmp X`: jump to an memory address specified by X (can be a label)

`jmp *R`: jump to the memory address specified in register R

`jmp *(R)`: jump to the memory address specified in the memory specified by register R

## Commands

Loops (for, while)

Switch Statements (switch)

## Exercises

To implement more complicated structures while minimizing the size of the assembly program, jumps are introduced.

## definition

`jmp X`: jump to an memory address specified by X (can be a label)

`jmp *R`: jump to the memory address specified in register R

`jmp *(R)`: jump to the memory address specified in the memory specified by register R

## Remark

*PC-relative encoding have two advantages:*

- ▶ *more compactly encoded instruction*
- ▶ *more portable code*

Conditional Jumps

Conditional Moves

## Logic Structures

Conditional Branches (if)

Loops (for, while)

Switch Statements (switch)

## Exercises

We can also use a constant table to refer to what's the jump destination.

### definition

An anchor label and an alignment specification.

# Jump Tables

We can also use a constant table to refer to what's the jump destination.

## definition

An anchor label and an alignment specification.

## structure

```
.section .rodata /* stands for read-only data */  
.align 8 /* specifies the alignment used in the table */  
.L4: /* the anchor label */  
.quad .L8  
.quad .L2  
...
```

## usage

`jmp .L2(,%rax,8):` jump to the label specified by `%rax`

## Exercises

# Jump Tables

We can also use a constant table to refer to what's the jump destination.

## definition

An anchor label and an alignment specification.

## structure

```
.section .rodata /* stands for read-only data */  
.align 8 /* specifies the alignment used in the table */  
.L4: /* the anchor label */  
.quad .L8  
.quad .L2  
...
```

## usage

`jmp .L2(,%rax,8)`: jump to the label specified by `%rax`

## Remark

*Jump tables help perform jumps automatically.*

# Conditional Jumps

To harness the power of condition codes, conditional jumps are introduced.

## definition

`jX D` (X is a condition): jump to the address specified by D if X is satisfied.

## Remark

*Conditional jump are the reason why we could implement logic structure.*

## Exercises

In the assembly code provided in the CSAPP textbook and the bomb lab, sometimes **ret** is written as **rep ret** or **repz ret**.

So, why are they there in the first place?

In the assembly code provided in the CSAPP textbook and the bomb lab, sometimes **ret** is written as **rep ret** or **repz ret**.

So, why are they there in the first place?

### Answer

They are only used for **AMD** CPUs since these CPUs cannot handle the return address if **ret** is reached from a conditional jump. In another word, **rep** and **repz** are meaningless occupiers that could avoid this situation from happening.

## Exercises

# Condition Moves

Before diving into details why we introduce conditional moves, we first review the definition of conditional moves(`cmov`).

## definition

`cmovSX R1 R2` (S is the size and X is a condition): if X is satisfied, move data from R1 to R2.

R1, R2 cannot both be memory address.

## Example

```
movq %rdi, %rax
subq %rsi, %rax
movq %rsi, %rdx
subq %rdi, %rdx
cmpq %rsi, %rdi
cmovge %rdx, %rax
ret
```

# Condition Moves

So, why use cmov?

## Commands

- Program Counter
- Condition Codes
- Compare

- Jumps
- Jump Tables

## Conditional Commands

- Conditional Jumps
- Conditional Moves**

## Logic Structures

- Conditional Branches (if)
- Loops (for, while)
- Switch Statements (switch)

## Exercises

# Condition Moves

So, why use cmov?

- ▶ Advantages
  - ▶ Save space
  - ▶ Enhanced performance on pipelined CPUs (while jmp perform terribly) due to **condition code transfers**.

## Remark

*Pipelined CPU achieves high performance by overlapping the steps of the successive instructions.*

## Commands

### Exercises

# Condition Moves

So, why use cmov?

- ▶ Advantages
  - ▶ Save space
  - ▶ Enhanced performance on pipelined CPUs (while jmp perform terribly) due to **condition code transfers**.
- ▶ Disadvantages
  - ▶ May break the structure of assembly code
  - ▶ Increase the calculation workload
  - ▶ Forbidden in some cases
- ▶ Bad cases
  - ▶ Expensive evaluations: function-involved
  - ▶ Risky computation:  $p ? *p : 0$
  - ▶ Computations with side effects:  $+=, *=$

## Remark

*Pipelined CPU achieves high performance by overlapping the steps of the successive instructions.*

Switch Statements (switch)

## Exercises

## Implementation

conditional jumps

## Example

Implement a loop using `%rdi` and `%rsi` where the outer `i` iterates from 0 to 9 and the inner one iterates from `i` to 9

# for,while

## Answer

```
mov $0 %rdi
jmp .CHECK1
.LOOP1: mov %rdi %rsi
jmp .CHECK2
.LOOP2:
... //do stuff
.CHECK2:
cmp %rsi $9
jle .LOOP2
.CHECK1:
cmp %rdi $9
jle .LOOP1
```

- Conditional Branches (if)
- Loops (for, while)**
- Switch Statements (switch)

## Exercises

# switch

## Implementation

jump tables

## Example

Implement a function on a 64x machine to jump to .L1 when %rax is prime and .L0 when it is not. ( $\%rax \in \{1, 2, 3, 4\}$ )

## Answer

```
.section .rodata
.align 8
.ANCHOR:
.quad .L0
.quad .L1
.quad .L1
.quad .L0
...
jmp .ANCHOR(,%rax,$8)
```

# Exercises

Implemented on a x86-64 AMD machine.

```
function f(int a, int b, char flag){  
    return flag?abs(a-b):-abs(a-b);  
}
```

```
pushq %rbp
```

```
--(1)-- %dl %rdx
```

```
--(2)-- %rsi %rdi
```

```
--(3)-- %rbp
```

```
movzbq %bpl %rbp
```

```
--(4)-- %rbp %rdx
```

```
jnz .L1
```

```
--(2)-- %rsi %rdi
```

```
--(5)-- %rbp
```

```
movzbq %bpl %rbp
```

```
--(6)-- %rdx %rbp
```

```
--(7)-- .L1
```

```
mov %rdi %rax
```

```
sub --(8)-- --(9)--
```
